Occupancy detection modelling with ROccuPy

```
# Ensure everything is clean
rm(list=ls())
library(roccupy)
```

Let's first make sure reticulate works as needed. Note that this will depend on your setup. I'm using reticulate with conda and an environment called pymc3, but you will need to change this to your own version.

```
# If you are running this yourself, please make sure that reticulate uses the
# correct virtual environment.
# Set this to FALSE if you don't have a GPU.
roccupy::set_gpu(TRUE)
```

This document shows how on a small subset of eBird using 8,000 checklists and 32 species.

The data format

As you can see, the dataset consists of four different items. Let's go through these in turn.

```
head(eBird$X checklist)

                                                                                 False
```

X_env contains the environmental covariates thought to influence whether a species is present or absent at each site. Because there are repeat visits, X_env will typically have fewer rows than X_checklist: there are fewer sites than observations.

```
head(eBird$checklist_cell_ids)
#> [1] 287 3337 3099 1445 2556 907
```

Finally, the checklist_cell_ids provide the link between sites and observations. Each entry specifies which site (or cell) the observation was made in. For example, in this case, the first observation was made in site 287. Please note that sites are numbered from zero, so this would correspond to X_env[288], for example. Storing the data in this way is useful as some sites are visited far more frequently than others. You can see this here:

```
head(sort(table(eBird$checklist_cell_ids), decreasing = TRUE), 20)

```

Fitting a model to eBird

We'll now walk through the steps required to fit a multi-species occupancy detection model to this dataset using variational inference.

```
# To make the code a little less cluttered, we can attach the entries in "eBird":
attach(eBird, warn.conflicts = FALSE)

# We'll want to scale the continuous environment variables.
bio_cols <- colnames(X_env)[grepl('bio', colnames(X_env))]

X_env_bio <- X_env[, bio_cols]
X_env_bio_scaled <- scale(X_env_bio)

# We also want to use the "has_" covariates:
discrete_cols <- X_env[, grepl('has_', colnames(X_env))] == 'True'

full_X_env <- cbind(X_env_bio_scaled, discrete_cols)</pre>
```

```
# We need to standardise log_duration:
log_durations <- X_checklist$log_duration
log_duration_mean <- mean(log_durations)
log_duration_sd <- sd(log_durations)

X_checklist$log_duration_z <- (log_durations - log_duration_mean) / log_duration_sd</pre>
```

We've now preprocessed our environmental covariates so that the continuous covariates are scaled. You can take a look at the covariates we'll use here:

```
full_X_env <- data.frame(full_X_env)</pre>
head(full_X_env)

fit_model <- msod_vi(env_formula, obs_formula, full_X_env, X_checklist,</pre>
                        y_checklist = y_checklist,
                        checklist_cell_ids = checklist_cell_ids, M=20L)
end_time <- Sys.time()</pre>
print(end_time - start_time)
#> Time difference of 40.54718 secs
# We can extract the draws for the coefficients as follows:
coef_draws <- coef(fit_model)</pre>
# This is a list:
names(coef draws)
#> [1] "env_intercepts" "env_slopes" "obs_prior_means" "obs_prior_sds"
#> [5] "obs_slopes"
```

These are the inferences made by the model. We can go through a little bit of maths to understand what they mean.

First, we model the probability that species j is present at site i. We can write this as:

$$y_{ij} \sim \text{Bern}(\Psi_{ij}),$$
 (1)

$$logit(\Psi_{ij}) = x_i^{\mathsf{T}} \beta_j + \gamma_j, \tag{2}$$

$$\beta_i \stackrel{iid}{\sim} \mathcal{N}(0, I),$$
 (3)

$$\gamma_i \stackrel{iid}{\sim} \mathcal{N}(0, 10^2).$$
 (4)

The γ_i here are the env_intercepts, and the β_i are the env_slopes reported by the model.

Next, we can take a look at the detection part of the model:

$$p(s_{ijk} = 1 \mid y_{ij} = 1) = p_{ijk}, (5)$$

$$logit(p_{ijk}) = x_{ik}^{(obs)\mathsf{T}} \beta_j^{(obs)}, \tag{6}$$

where

$$\beta_{jl}^{(obs)} \stackrel{iid}{\sim} \mathcal{N}(\mu_l, \sigma_l^2),$$
 (7)

$$\mu_l \stackrel{iid}{\sim} \mathcal{N}(0,1),$$
 (8)

$$\sigma_l \stackrel{iid}{\sim} \mathcal{H}(1).$$
 (9)

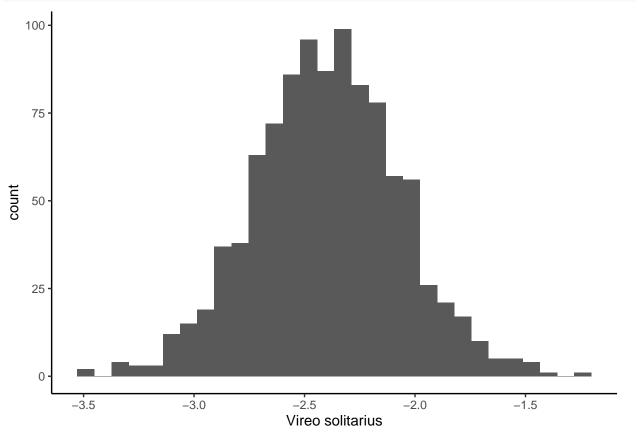

This says that the (logit) of the probability of detecting species j at site i on the k-th visit, if it is present, is given by a linear function of the observation covariates and species-specific observation coefficients $\beta_j^{(obs)}$. These species coefficients are the obs_slopes in the model results. The next three lines specify the hierarchical prior on the observation covariates. The group means μ_l and group standard deviations σ_l are reported in obs_prior_means and obs_prior_sds, respectively. The \mathcal{H} denotes the half-normal distribution.

We will now quickly take a look at some of the results. First, let's look at the environment intercepts:

```
library(ggplot2)
intercept_draws <- coef_draws$env_intercepts

p <- ggplot(intercept_draws, aes(x=`Vireo solitarius`)) + geom_histogram() + theme_classic()

p
#> `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
```

We can see that *Vireo solitarius*, the Blue-headed Vireo, has a mean intercept of around -2.2 or so. We can also take a look at its estimates for environmental response:

```
head(coef_draws$env_slopes$`Vireo solitarius`)

These are 1000 draws. We can summarise them using their means and sds:

```
mean_slopes <- colMeans(coef_draws$env_slopes$`Vireo solitarius`)</pre>
sd_slopes <- apply(coef_draws$env_slopes$`Vireo solitarius`, 2, sd)</pre>
cbind(mean_slopes, sd_slopes)

                               0.119025655 0.4699266
#> has_evergreen_forest
                              0.551370178 0.7370500
```

It appears that bio5 seems to be associated with a decreased probability of presence for this bird. What's this one?

```
ml_tools$sdm$bioclim_lookup$bio5
#> [1] "Max Temperature of Warmest Month"
```

Indeed, looking at the range map on All About Birds, this seems plausible, as this species tends to breed in the North of the US, where it is cool.

Let's now take a look at the observation process. Summarising the group means gives:

```
colMeans(coef_draws$obs_prior_means)
#>
                           Intercept
                                           protocol_type[T.Stationary]
#>
                         -2.49532303
                                                            -0.42658705
#>
         protocol_type[T.Traveling]
                                                  daytimes_alt[T.dusk]
#>
                          0.08725008
                                                            -1.10831083
#>
      daytimes_alt[T.early-evening]
                                         daytimes_alt[T.early-morning]
#>
                         -0.13811998
                                                             0.09534828
       daytimes_alt[T.late-evening]
                                          daytimes_alt[T.late-morning]
#>
#>
                         -0.24117575
                                                            -0.09702172
            daytimes_alt[T.mid-day]
#>
                                                 daytimes_alt[T.night]
                         -0.26705908
                                                            -1.79574412
#>
   dominant_land_cover[T.developed]
                                         dominant_land_cover[T.forest]
#>
                         -0.62698741
                                                            -0.34092793
#>
       dominant_land_cover[T.water]
                                                         log_duration_z
                         -0.46125448
                                                             0.50315148
```

And the group standard deviations are:

```
colMeans(coef_draws$obs_prior_sds)
                           Intercept
#>
                                           protocol_type[T.Stationary]
#>
                          1.54725211
                                                             0.48093480
#>
         protocol_type[T.Traveling]

#> daytimes_alt[T.night]
                                    -2.78446649 1.73184793
#> dominant_land_cover[T.developed] -0.76592235 0.54624868
#> dominant_land_cover[T.forest]
                                    1.55090084 0.19126190
#> dominant_land_cover[T.water]
                                    -1.07537557 0.47412258
#> log_duration_z
                                     0.47101515 0.17908677
```

This suggests, for example, that *Vireo solitarius* is considerably more likely to be detected in the forest than by water, which seems reasonable.

```
# How about a plot of detectability by day vs detectability by night?
obs_slopes <- coef_draws$obs_slopes</pre>
# This is a list of species names -> draws. Let's compute the means.
obs_slope_means <- lapply(obs_slopes, colMeans)</pre>
obs_slope_means <- data.frame(do.call(rbind, obs_slope_means), check.names = FALSE)
# For easier plotting:
obs_slope_means$species_name <- row.names(obs_slope_means)</pre>
head(obs_slope_means)
#>

# We can also predict. Here, let's just use the training data.
# If we want to predict the probabilities of presence, we can use:
env_preds <- predict(fit_model, full_X_env, type='env')</pre>
# If we want the probability of detection, we can use:
obs_preds <- predict(fit_model, full_X_env, X_checklist, type='obs')</pre>
A last noteworthy feature of the package is the ability to save and restore models. You can do this as follows:
# Save the model
save_model(fit_model, 'save_test')
# Restore it:
restored_model <- restore_model('./save_test/')</pre>
```
